

Aegis — AWS Deployment (Terraform), zero-trust

Zero-trust on AWS

1. Identity-based access everywhere: per-task IAM roles, RDS IAM auth, MSK IAM auth, KMS grants per service — no shared credentials. 2. Network as containment, not trust: tasks have no public IPs; SG-to-SG references only (ALB→gateway, gateway→services, services→data); data subnets have no internet route; VPC endpoints keep AWS traffic private. 3. Every service still validates JWT signature + issuer allowlist + scope on every request — the VPC is not a trust boundary. 4. Per-tenant issuers via the ALB/gateway host; per-tenant signing keys wrapped in KMS, rotated with overlap. 5. Encrypt everything: TLS 1.2+ in transit end-to-end, KMS at rest (RDS, EBS, logs, S3). 6. Detect + audit: CloudTrail (org trail), GuardDuty, Security Hub, WAF logs, VPC flow logs → CloudWatch; alerts on drift. 7. Supply chain: ECR scan-on-push, immutable tags, CI-only deploys via Terraform.
